

The affect-object advantage is far larger in sensory cortex than in the amygdala, in every arm

Sensory-cortex control (blue) shows a substantial affect advantage; the amygdala (grey) is at or below zero — significantly negative for single neurons and audio, and only a tiny near-floor increment in the movie (+0.0009, ~10× below fusiform). All four arms were re-run under corrected preprocessing. Units differ per arm.
